NCAR – Boulder – October 2009

Introduction

Where air is transported between troposphere and stratosphere, how is chemically processed during its passage through the transition layers and how CCMs represent these processes?

Convection, tropical upwelling and extratropical downwelling
Isentropic transport / barriers
Frontal uplift

Links between local and global scales
Different methodologies

Law, Haynes & Cox, WMO (2007), Chapter 2 on Very Short-Lived Halogenated Substances (VSLS)

Plan

In situ measurements: harmonising different sources to produce a global picture

Vertical coordinates

Tracer gradients

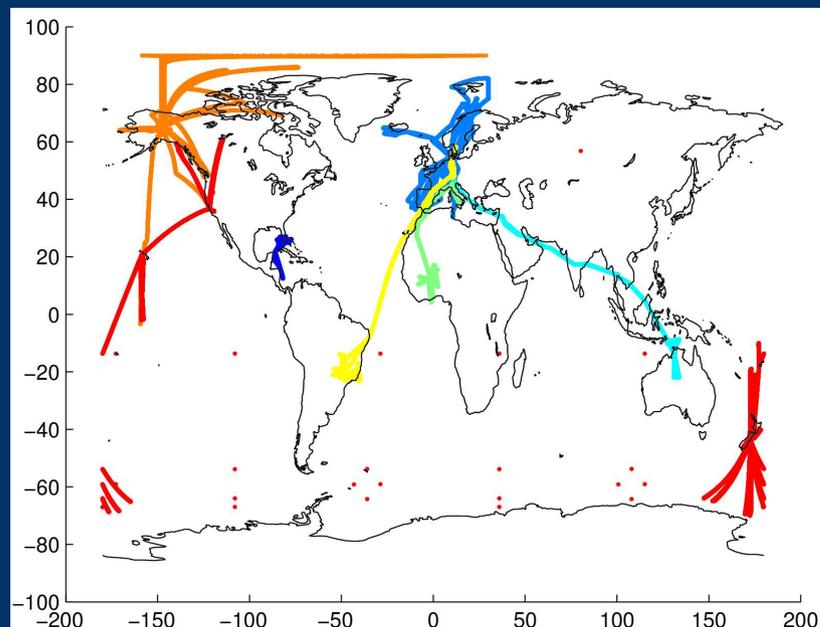

A Lagrangian perspective

Summary and outlook

In-situ measurements

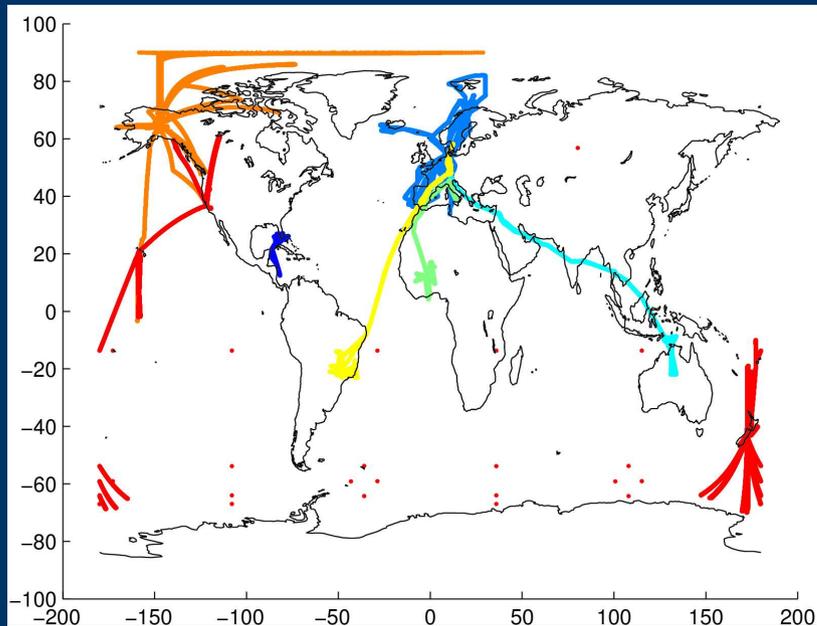

Development of an algorithm to integrate individual campaigns into a composite dataset of in situ measurements and then consistently calculate dynamical diagnostics from analysed winds.

ASHOE-MAESA, Polaris, Crystal-Face, SPURT, Hibiscus-Troccinox, AMMA and SCOUT-O3. More in progress

In-situ measurements

Tropopause theta (WMO definition)
Cold point theta

ASHOE-MAESA, Polaris, Crystal-Face, SPURT, Hibiscus-Troccinox, AMMA and SCOUT-O3. More in progress

In-situ measurements

1 234 241 measurement points

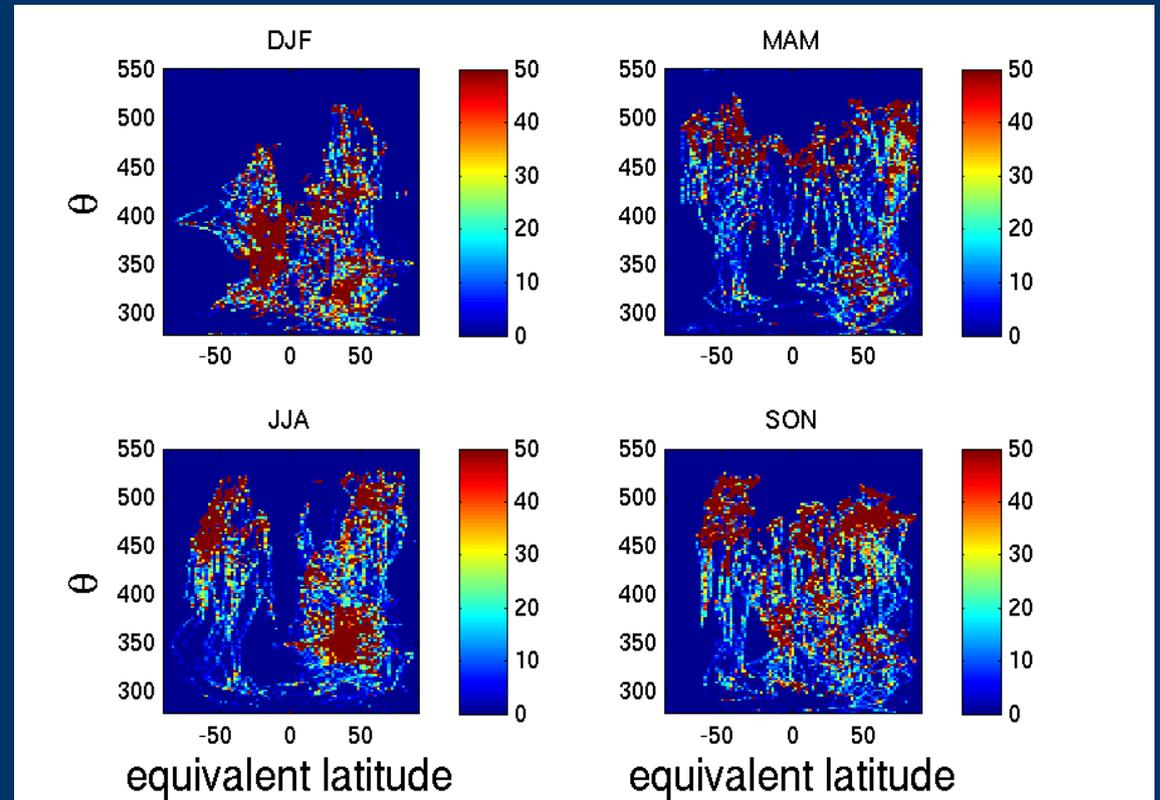

seasonal distribution:

DJF 331 661

MAM 265 607

JJA 313 054

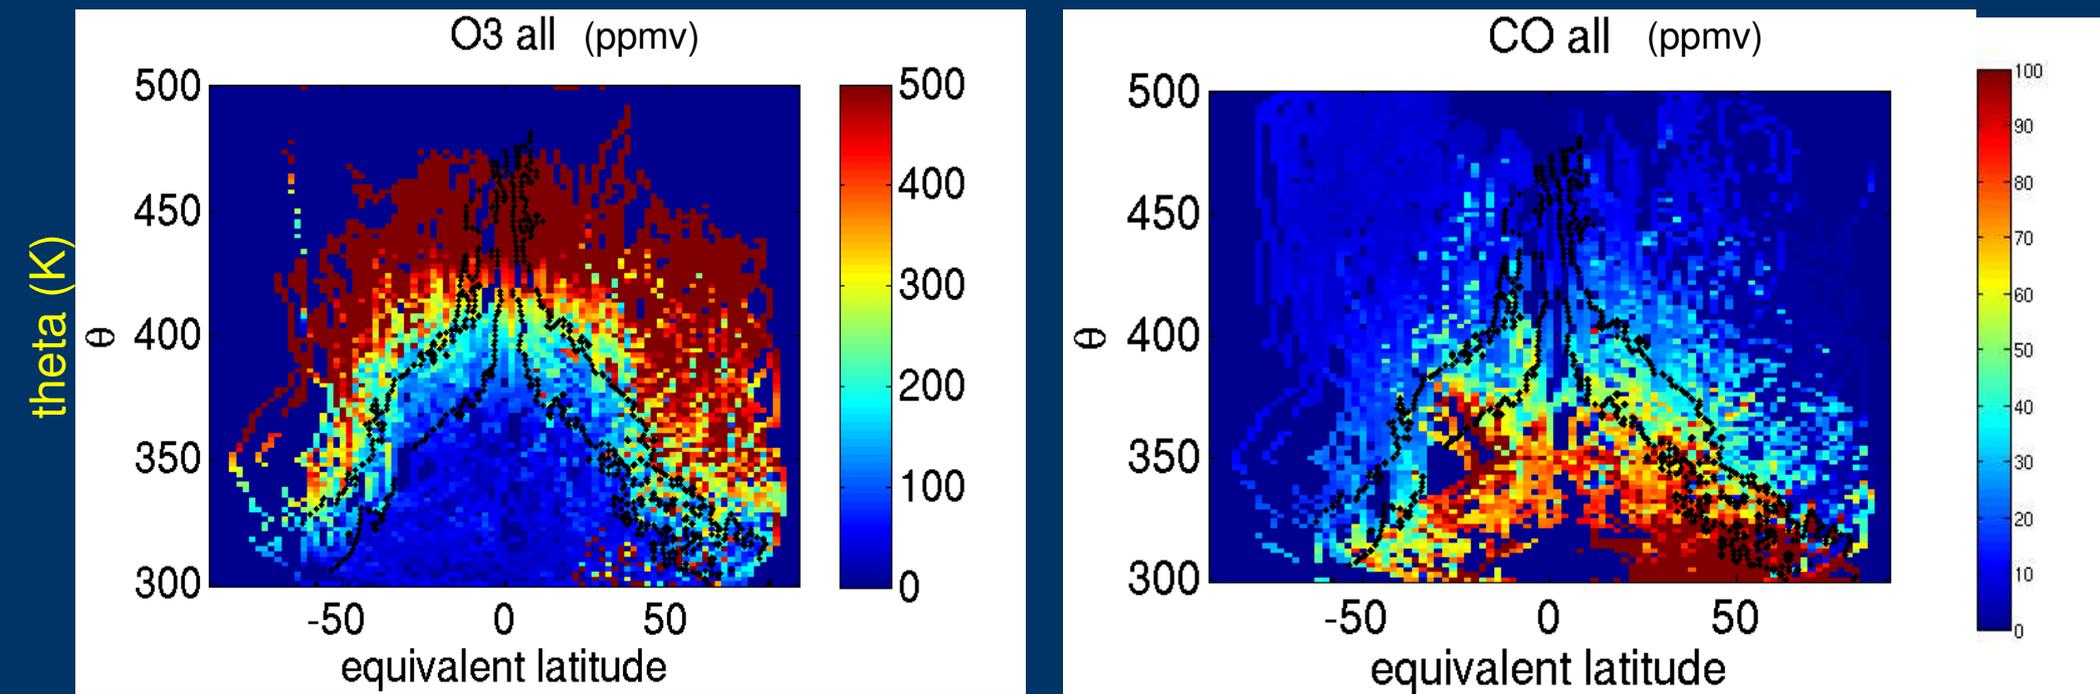

SON 323 919

Data points histogram in $2^\circ \times 2K$ bins

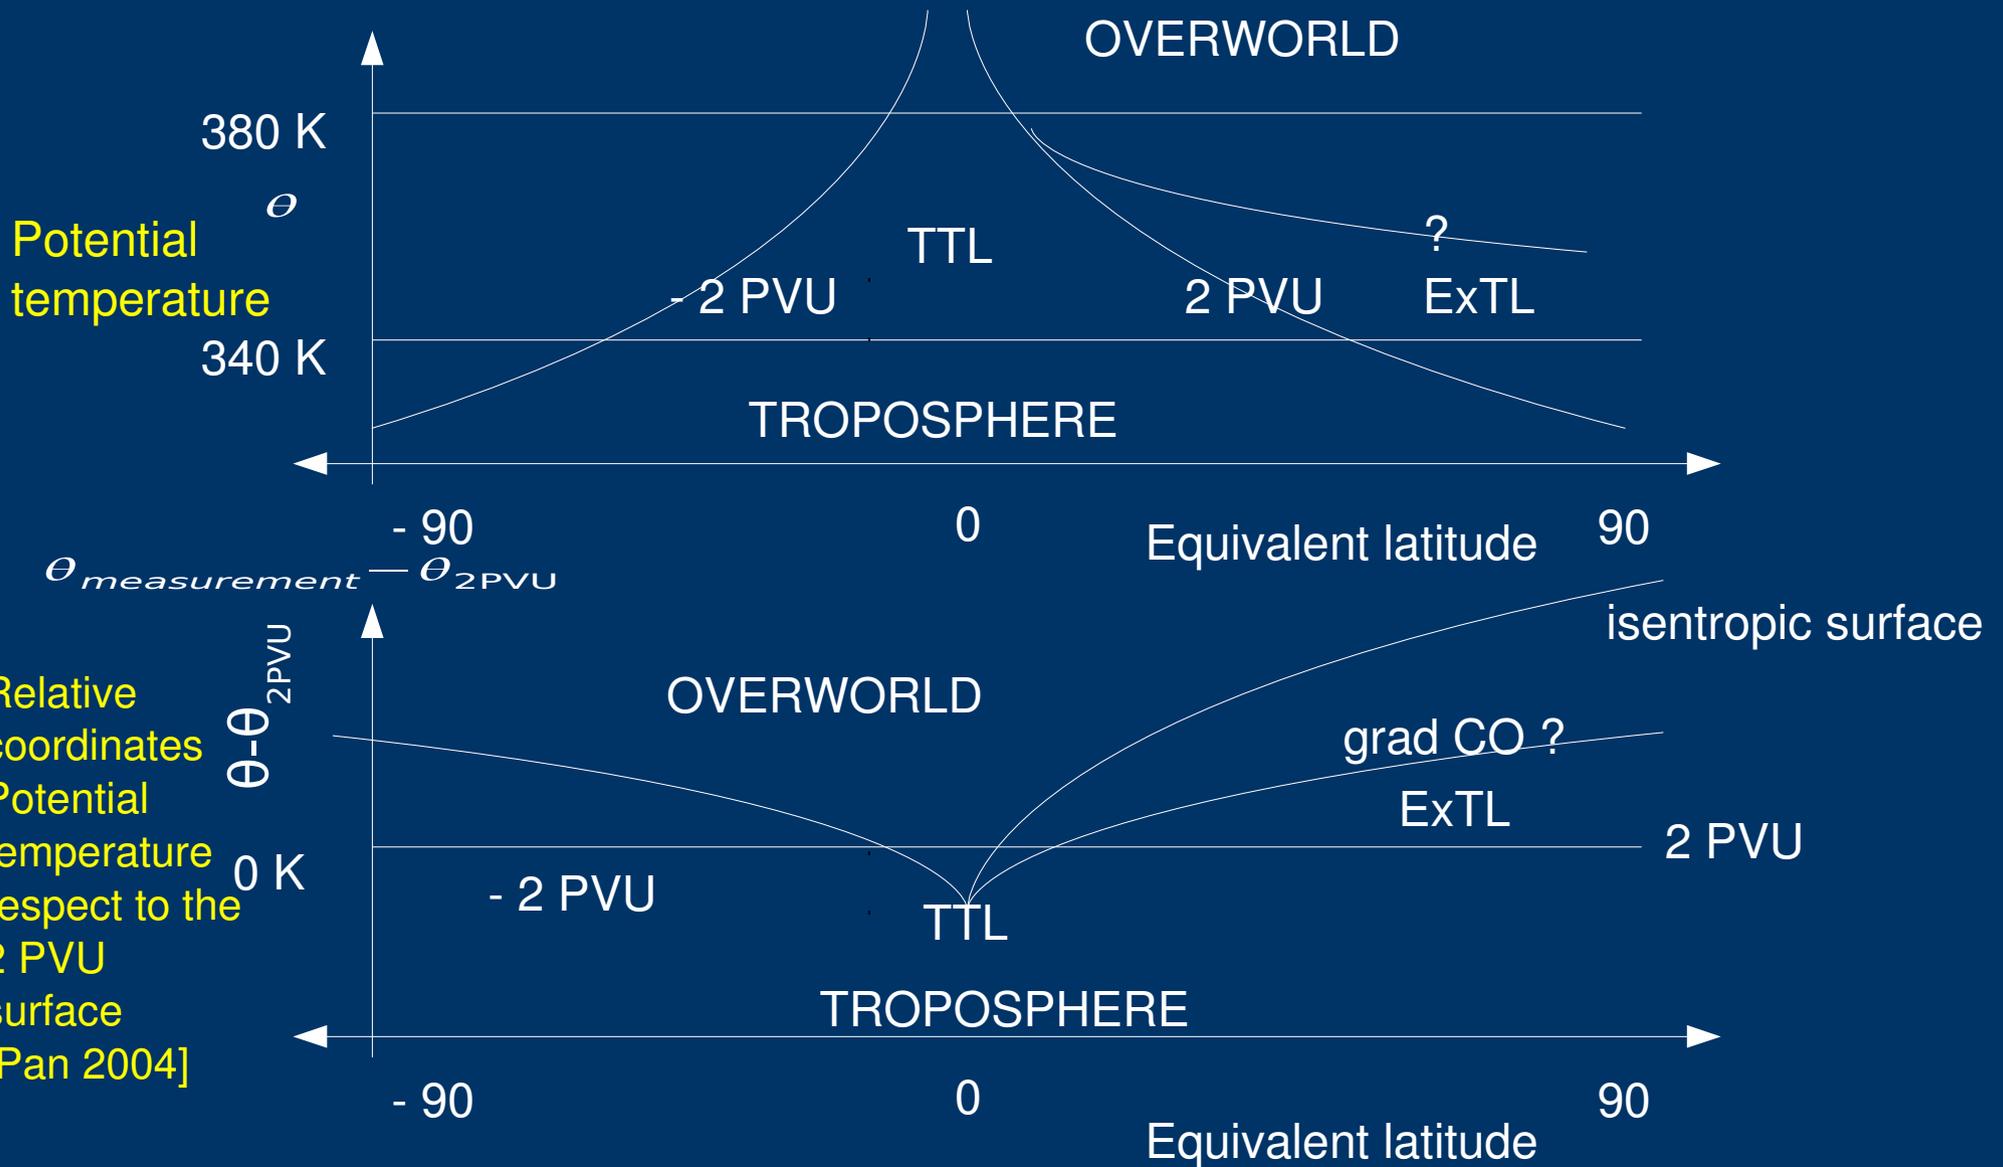

In-situ measurements

Composite of O₃ and CO *in-situ* measurements

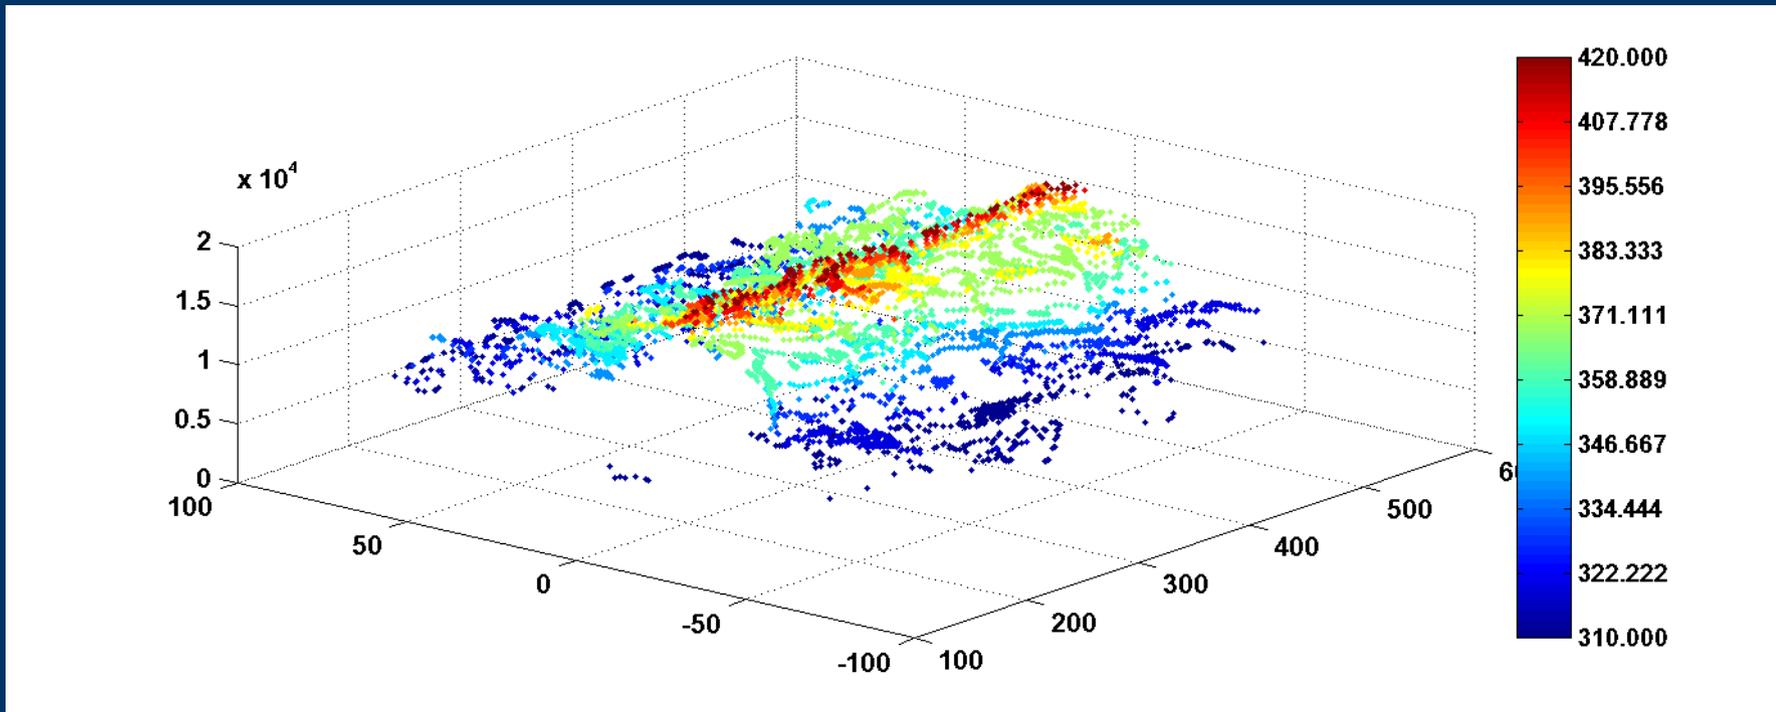

equivalent latitude

Change of vertical coordinates

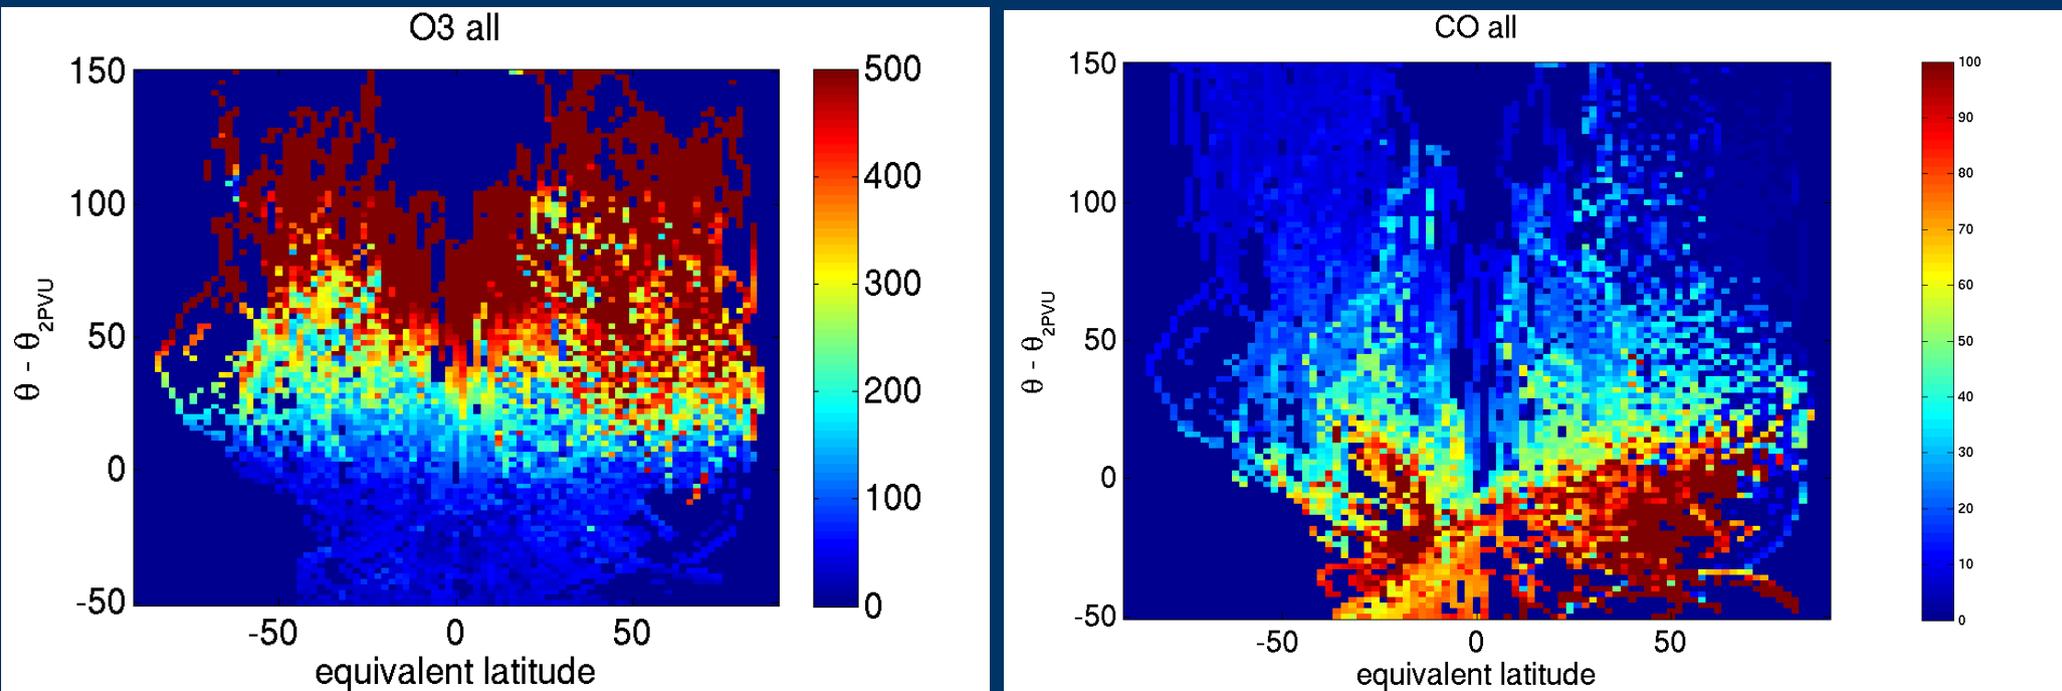

Height and θ of the 2 PVU surface

2 PVU surface height in meters .Color indicates potential temperature. A latitude circle of this surface intersects different isentropic levels.

Composite tracer data

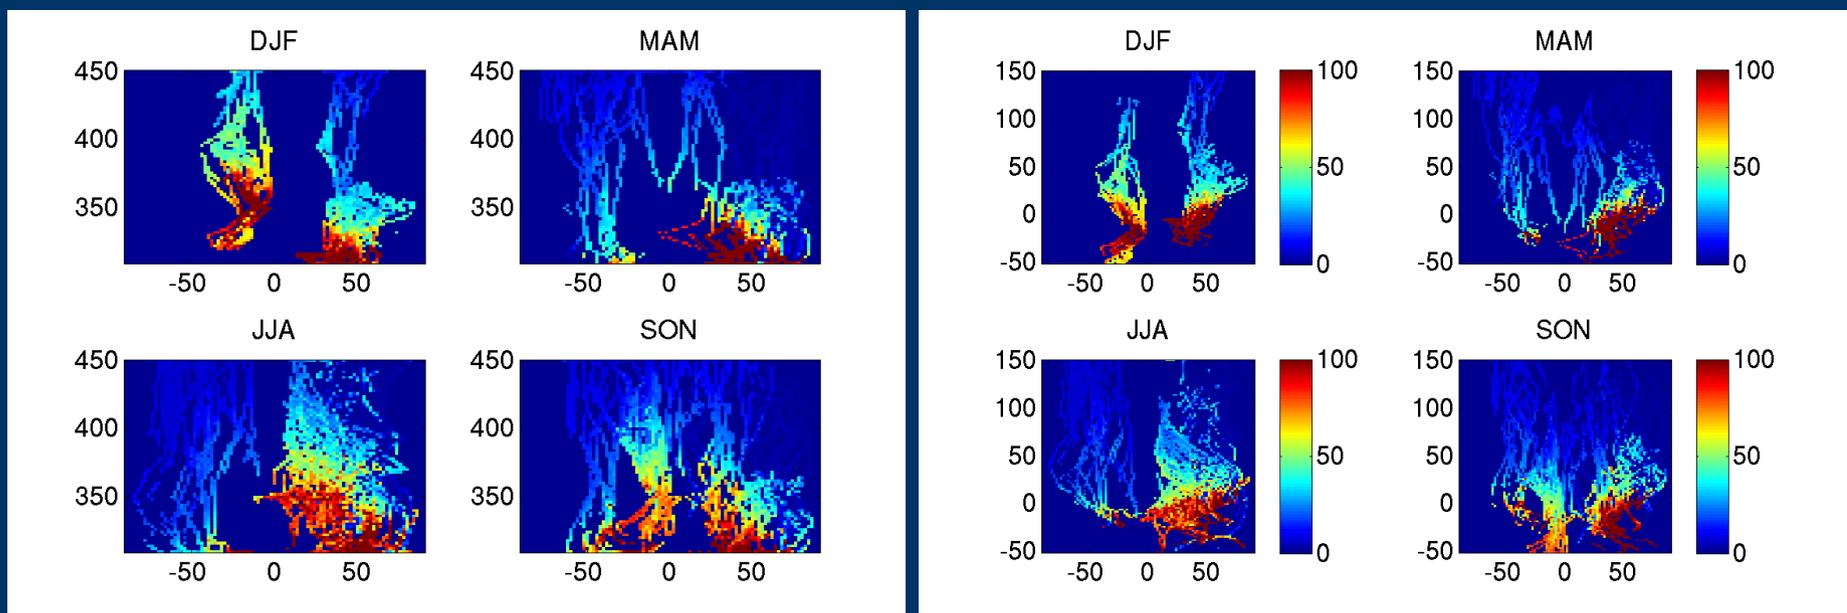

Composite of O3 and CO *in-situ* measurements (ppbv) in relative coordinates respect to the local 2 PVU surface.

For CO the NH is more regular (landmasses-pollution-forest fires).

SH two extrema: ASHOE on the Pacific+Troccinox over the Amazon in summer

CO seasonal variation

Seasonal composites of CO *in-situ* measurements

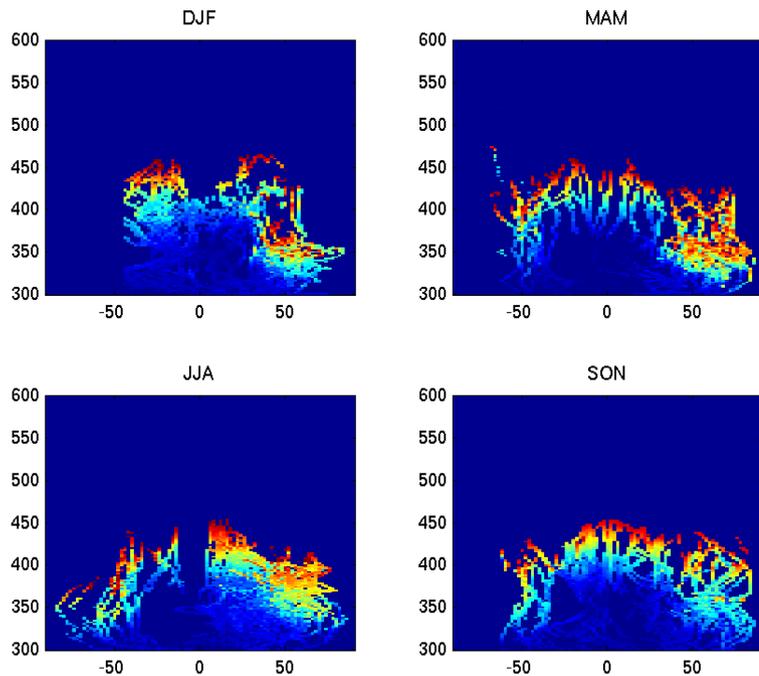

In theta coordinates

in relative coordinates respect
to the local 2 PVU surface

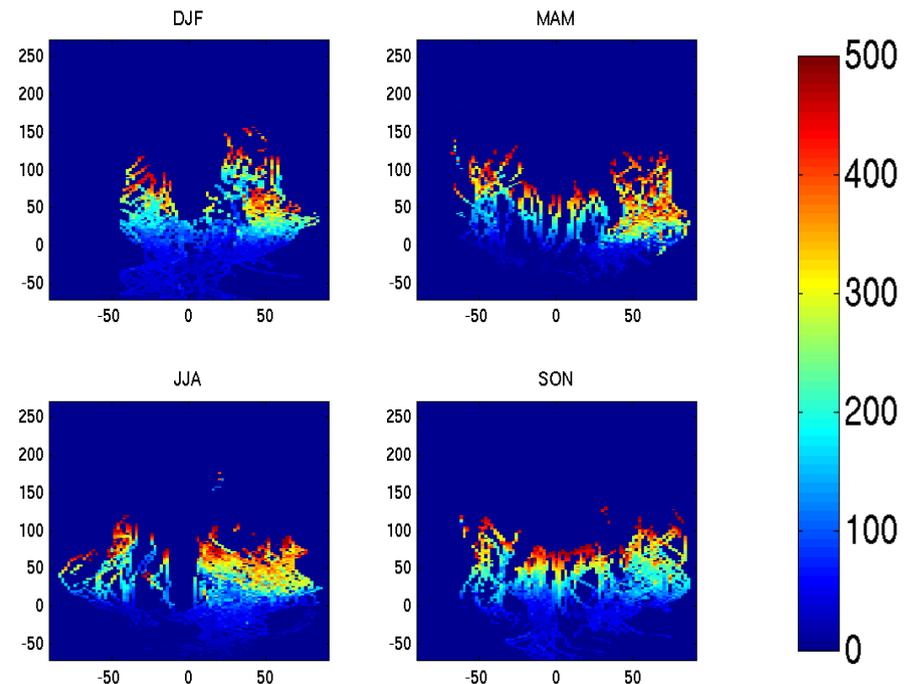

Less seasonal variation in delta theta coords.

O3 seasonal variation

Seasonal composites of O3 *in-situ* measurements

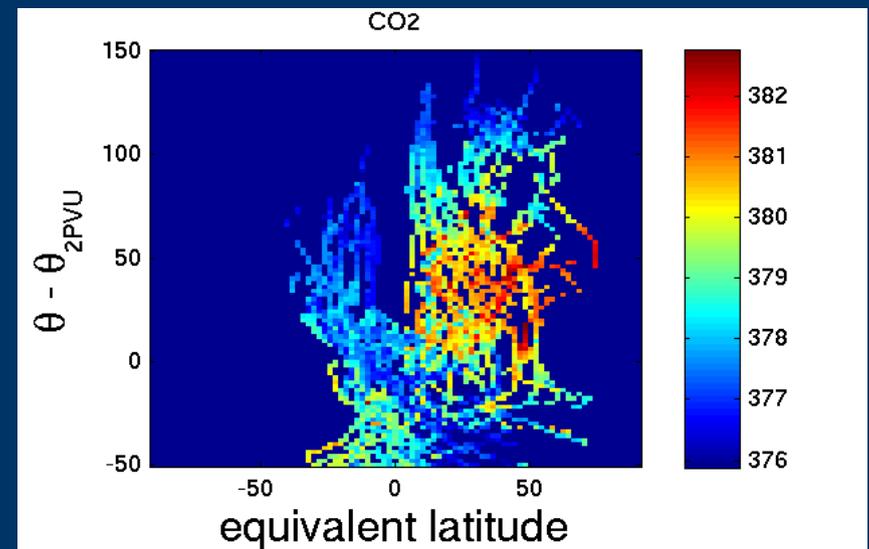

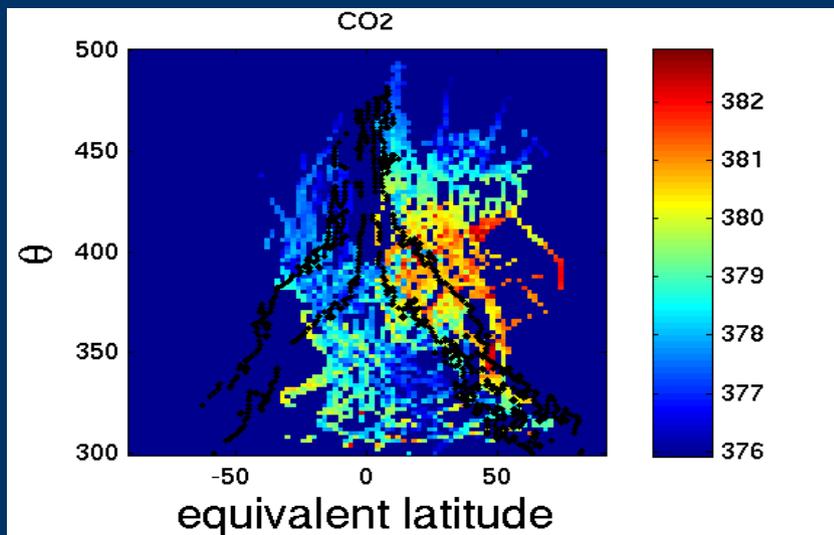

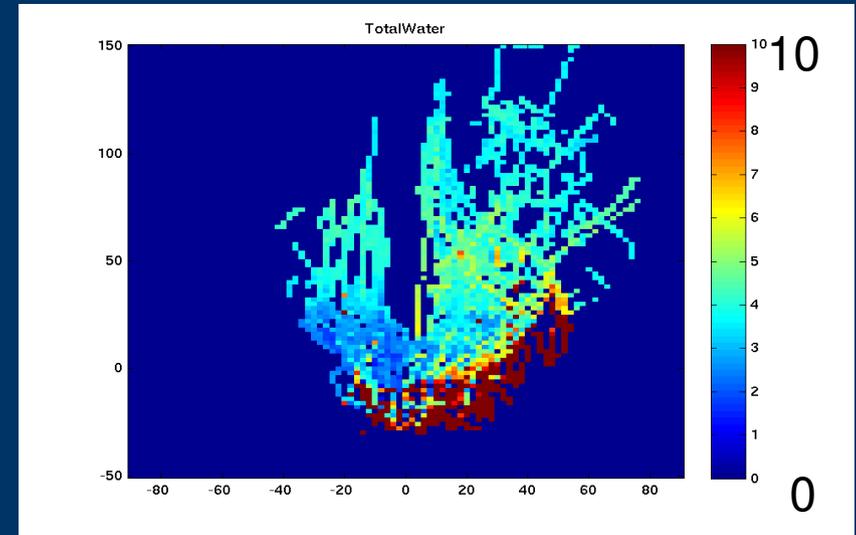

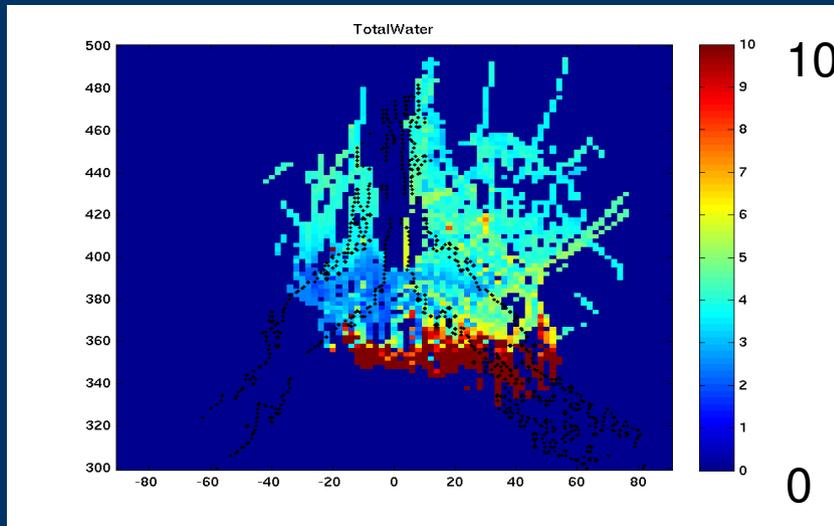

In theta coordinates

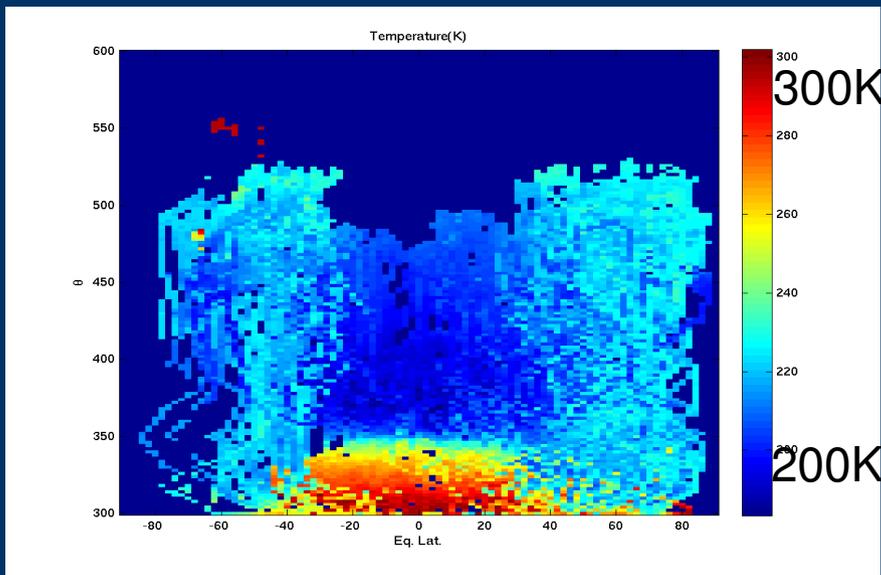

in relative coordinates respect
to the local 2 PVU surface

CO2 and H2O

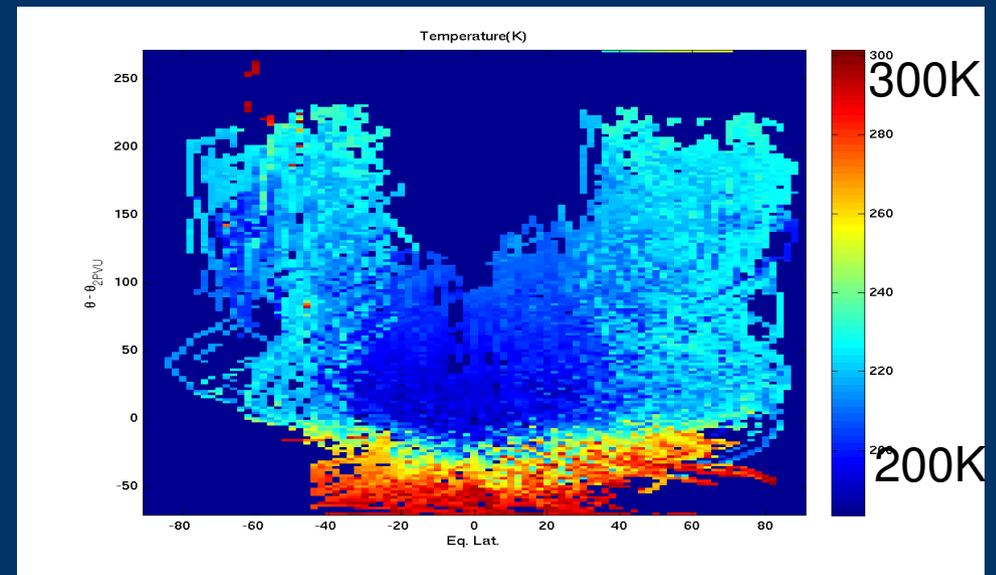

Water similar to CO. For CO2 there is no reason to follow the same pattern. Much longer lived

Temperature

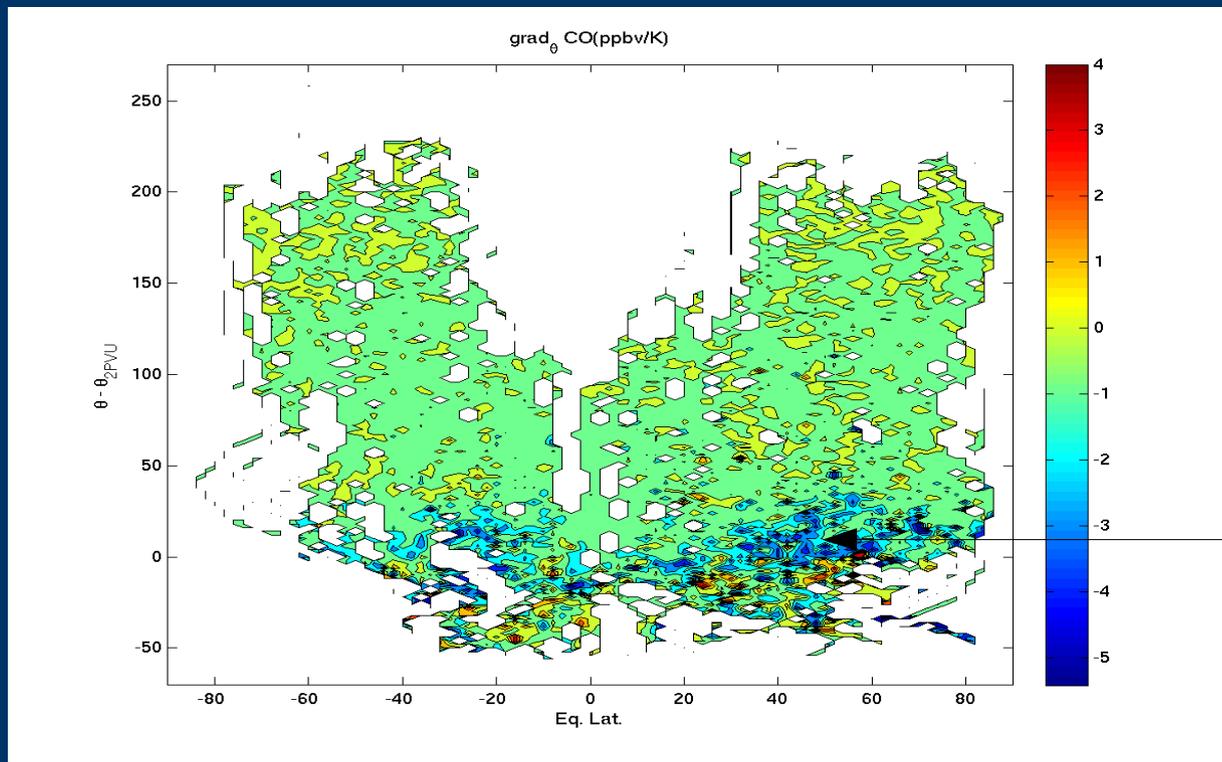

In theta coordinates

In delta theta
consistent with Hegglin 2009

CO cross isentropic gradient (calculated along flight tracks)

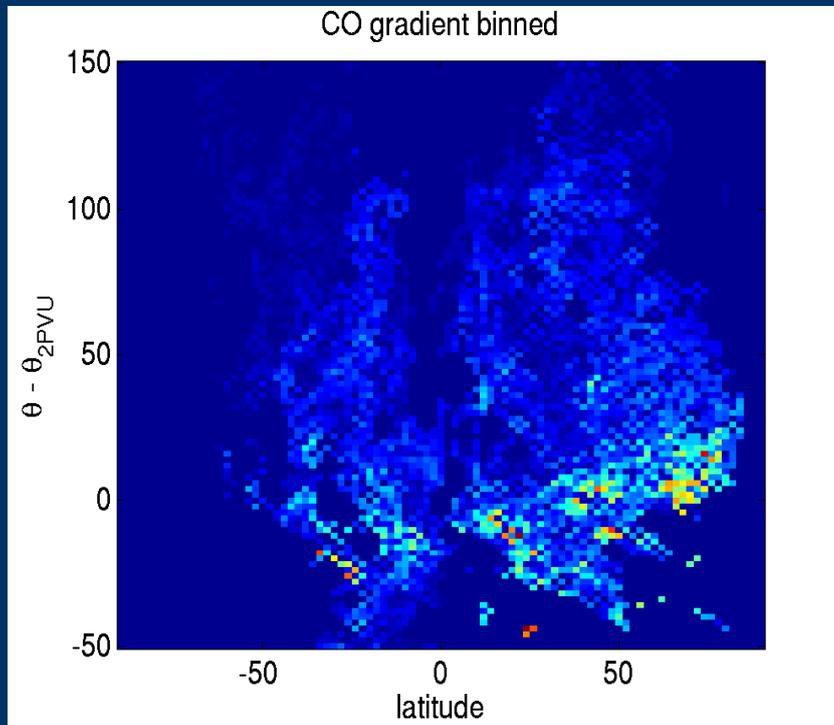

Gradient (calculated along the flight tracks) of CO in delta theta coordinates
Suggests strong gradients associated with the transition region

$$\text{Grad CO} = \Delta\text{CO}/\Delta\theta$$

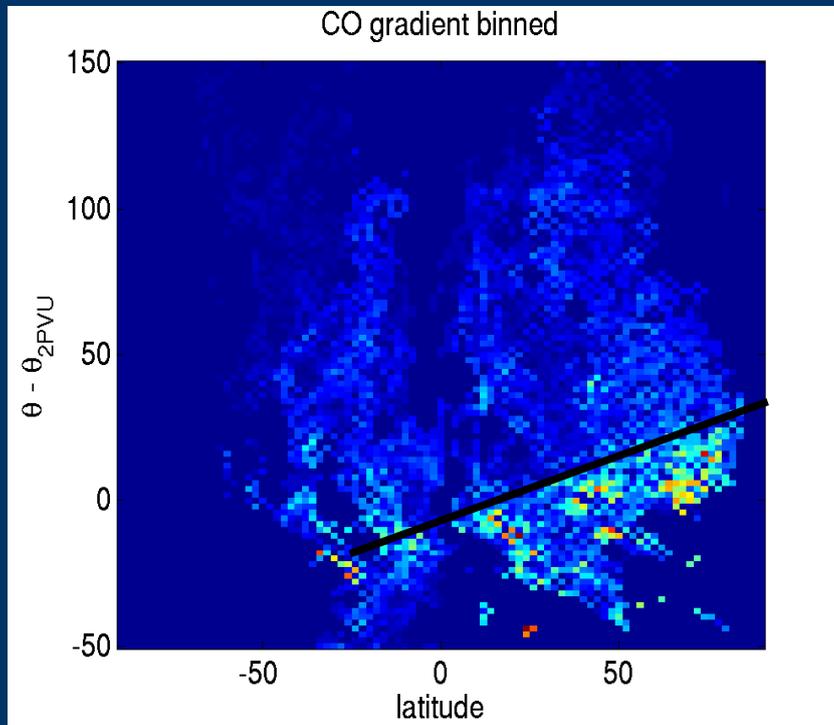

along flight path

CO gradients and theta surfaces

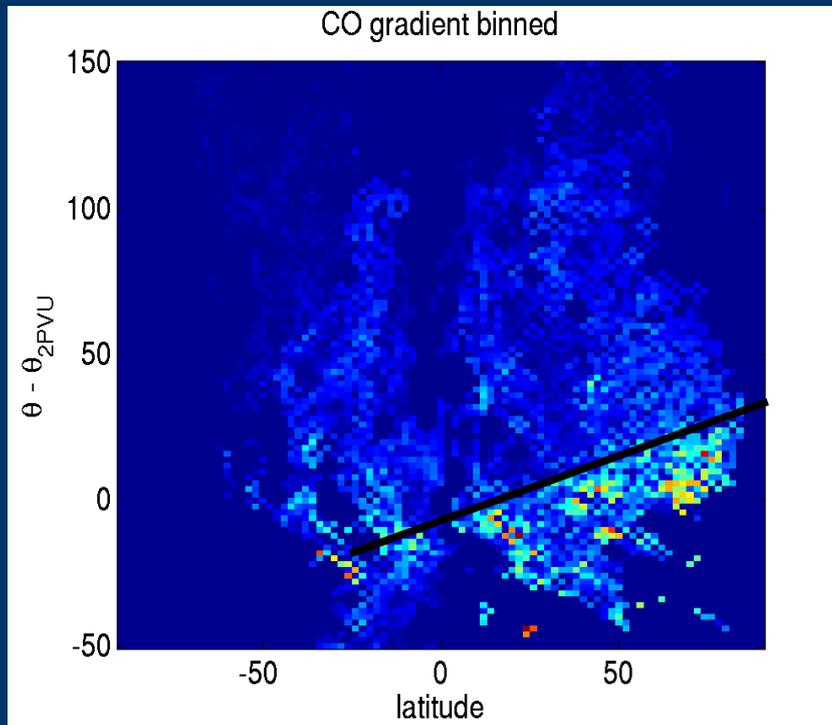

Total gradient CO
(theta + eq. latitude
arbitrary units)

CO gradients and theta surfaces

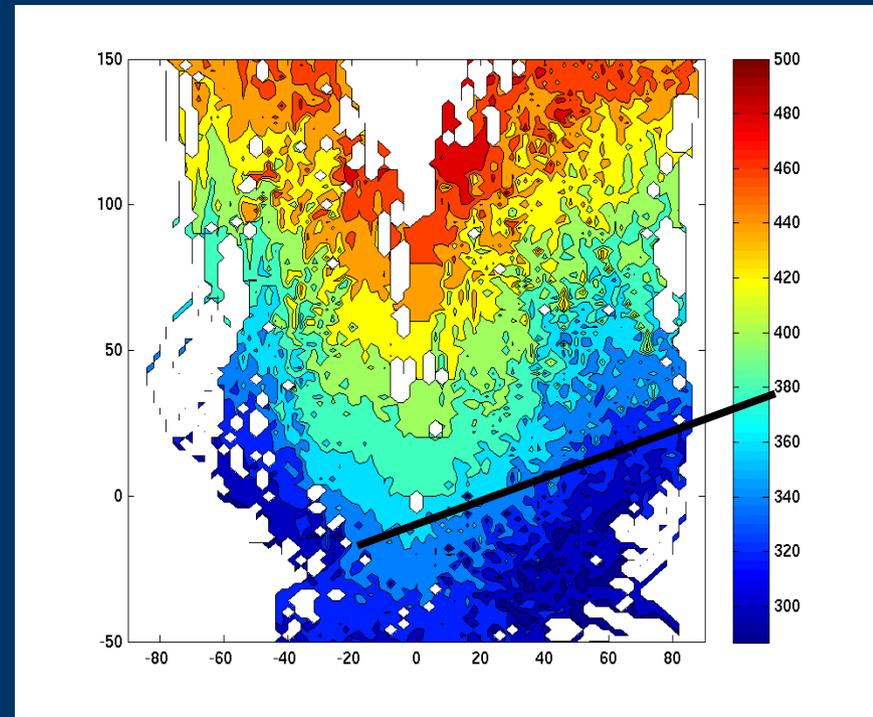

Total gradient CO
(theta + eq. latitude
arbitrary units)

CO gradients and theta surfaces

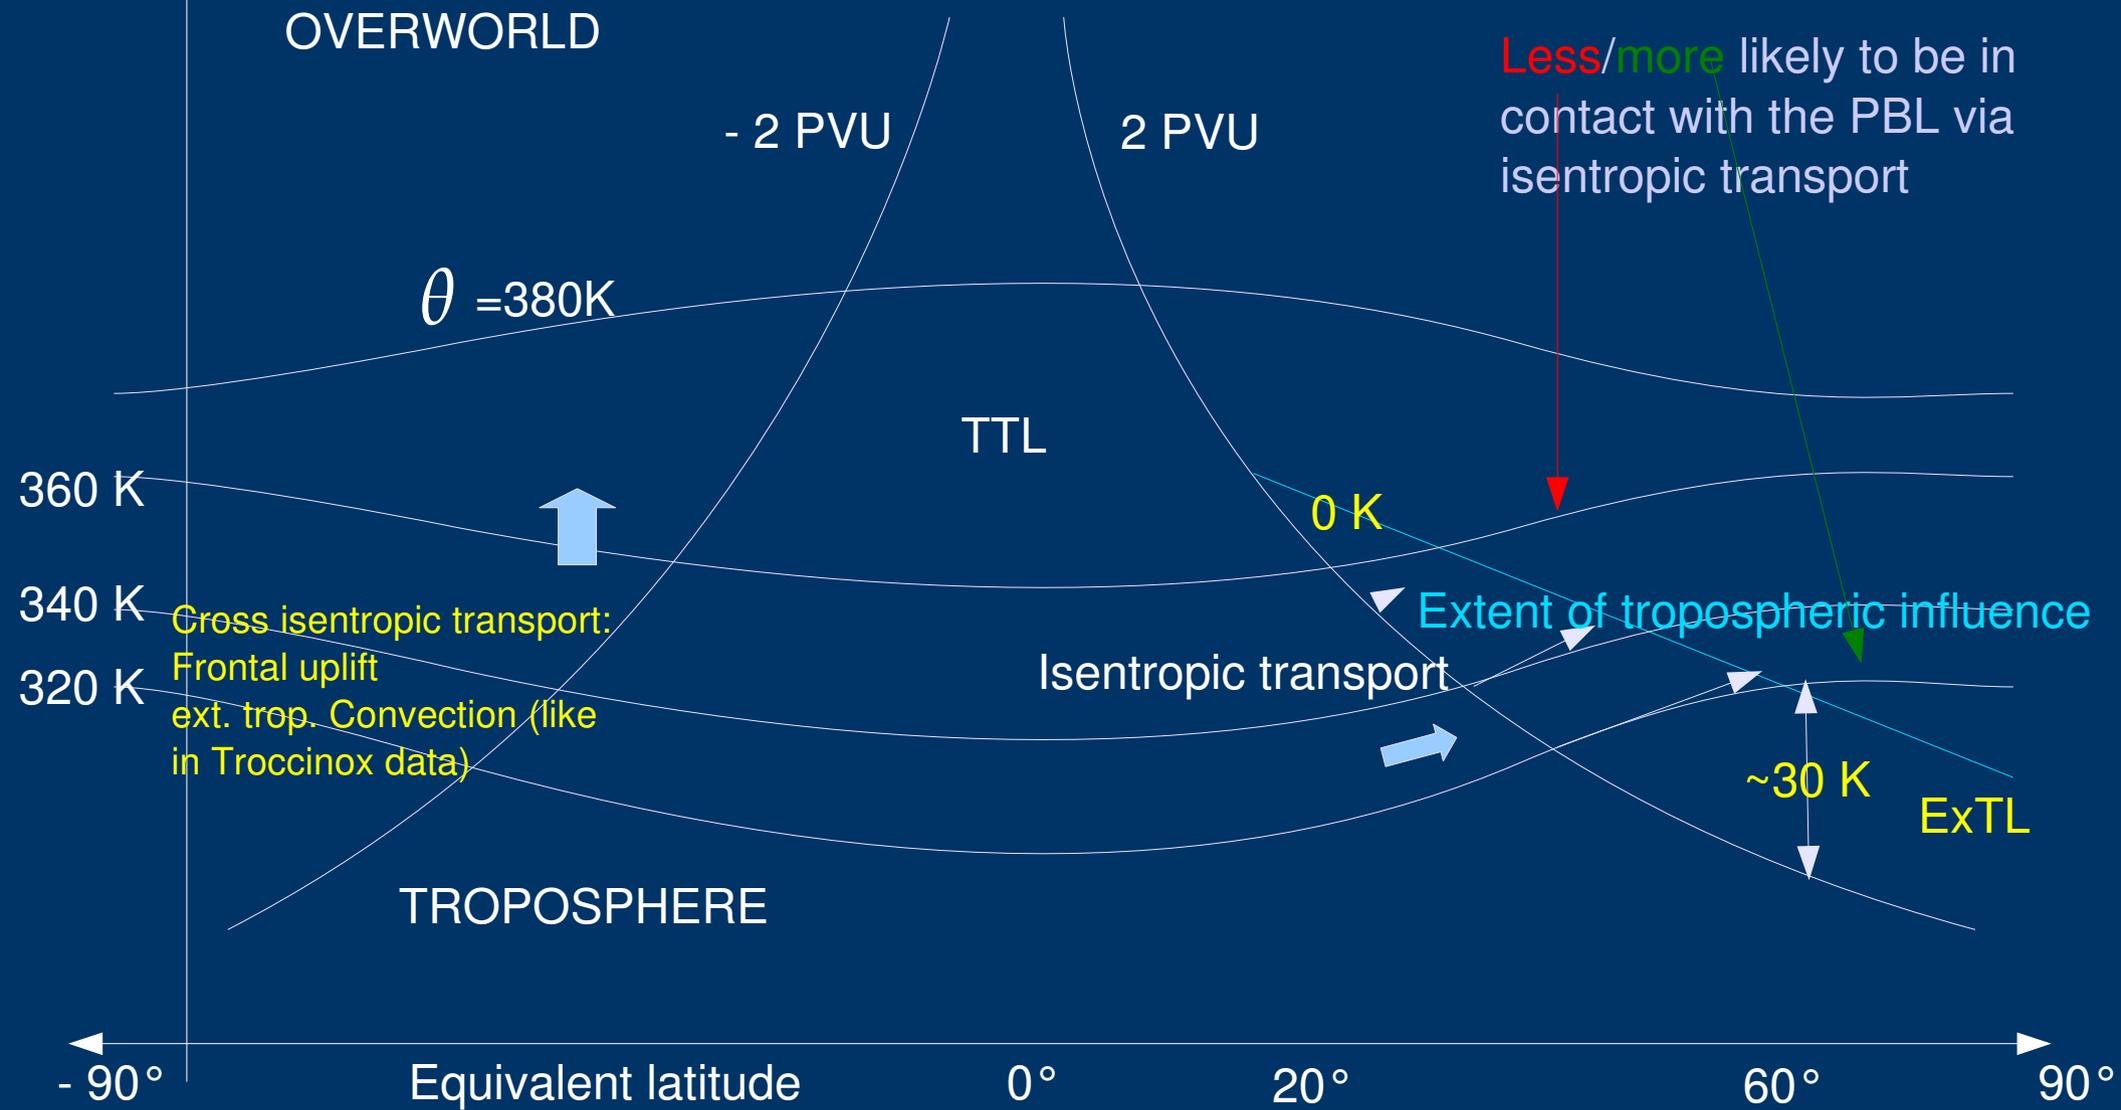

Total gradient CO
(theta + eq. latitude
arbitrary units)

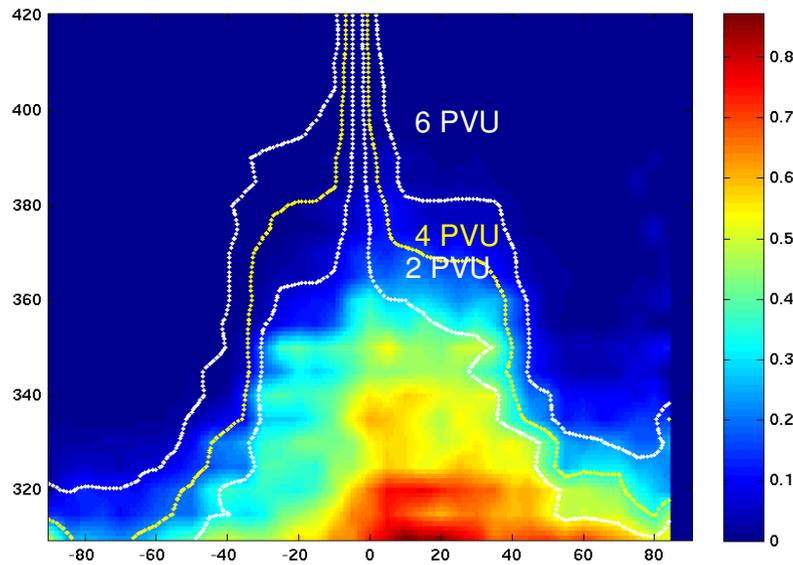

Theta in relative coordinates
In northern extratropics at 50k
above the 2 PVU surface
theta ~ 340 K

Conclusion 1: extent of isentropic + cross isentropic transport across the 2 PVU surface

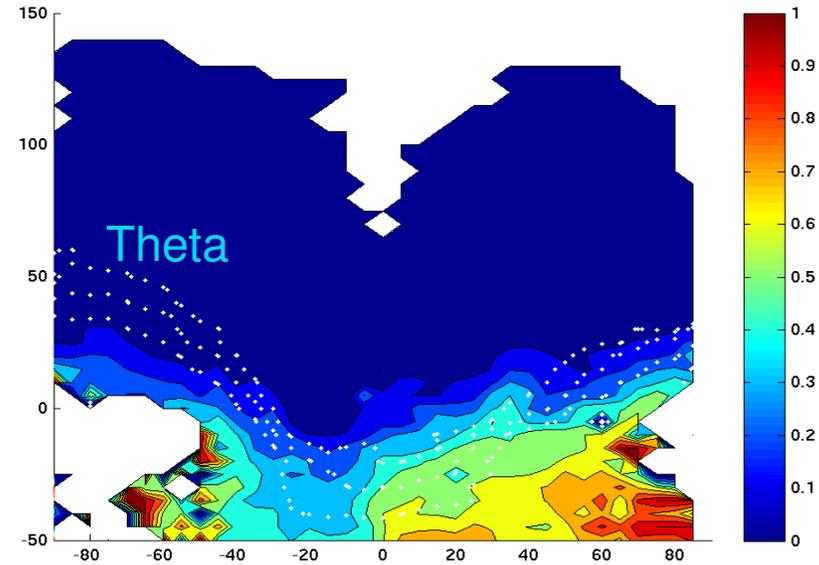

Discussion: consistent with the Lagrangian perspective

Chi: proportion of air in contact with the PBL within 1 month as in Berthet et al. 2007

Chi in theta coordinates

Chi in delta theta coordinates

Pure transport also displays isolines sloping between the constant PV and constant theta surfaces. The tilt respect to constant PVU surfaces is due mainly to isentropic transport but the iso chi does not seem to follow the isentropes as CO

CONCLUSIONS

Reduced seasonal variability and regular distribution in relative coordinates.

The SH data evidences impact of convection (Troccinox over Brazil) and tracer sources (less CO over the pacific -- more homogeneous in NH in space and time).

Extract information from small scale (well resolved in in situ measurements) to general features

Application to global model validation: alternative to pointwise comparison.

CONCLUSIONS

Increase of the thickness of the ExTL towards the poles:
~0 K above the 2 PVU surface at 20° to
~30 K in higher latitudes 60°/70°. Consistent with [Hoor
2004].

Similar pattern observed in T (c.f. [Hegglin 2009]) and
H₂O

Isentropic transport across constant PV surfaces also
present in chi (pure transport). Tracer (CO-chi) isolines
do not necessarily follow isentropes nor iso-PV
surfaces as all of them intersect.
